Data Mining

Ensemble Techniques

Introduction to Data Mining, 2nd Edition by Tan, Steinbach, Karpatne, Kumar

Ensemble Methods

 Construct a set of base classifiers learned from the training data

 Predict class label of test records by combining the predictions made by multiple classifiers (e.g., by taking majority vote)

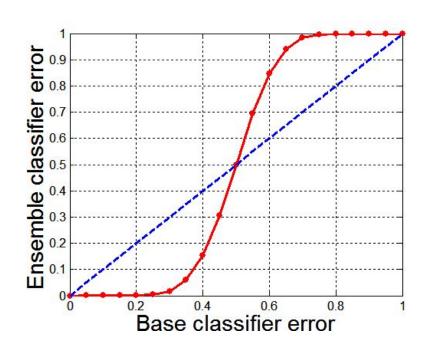

Example: Why Do Ensemble Methods Work?

- Suppose there are 25 base classifiers
 - Each classifier has error rate, ϵ = 0.35
 - Majority vote of classifiers used for classification
 - If all classifiers are identical:
 - Error rate of ensemble = ϵ (0.35)
 - If all classifiers are independent (errors are uncorrelated):
 - Error rate of ensemble = probability of having more than half of base classifiers being wrong

$$e_{\text{ensemble}} = \sum_{i=13}^{25} {25 \choose i} \epsilon^i (1-\epsilon)^{25-i} = 0.06$$

Necessary Conditions for Ensemble Methods

- Ensemble Methods work better than a single base classifier if:
 - 1. All base classifiers are independent of each other
 - All base classifiers perform better than random guessing (error rate < 0.5 for binary classification)

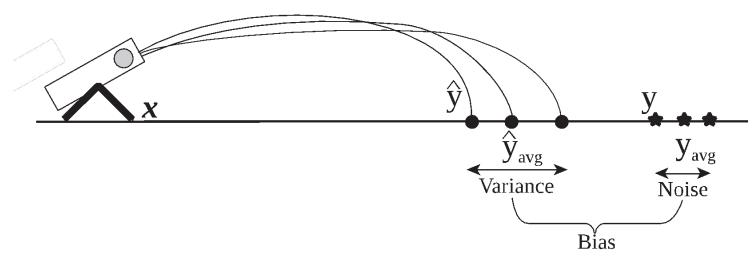

Classification error for an ensemble of 25 base classifiers, assuming their errors are uncorrelated.

Rationale for Ensemble Learning

- Ensemble Methods work best with unstable base classifiers
 - Classifiers that are sensitive to minor perturbations in training set, due to high model complexity
 - Examples: Unpruned decision trees, ANNs, ...
 - Low Bias in finding optimal decision boundary
 - High Variance for minor changes in training set or model selection procedure

Bias-Variance Decomposition

 Analogous problem of reaching a target y by firing projectiles from x (regression problem)

• For classification, gen. error or model m can be given by:

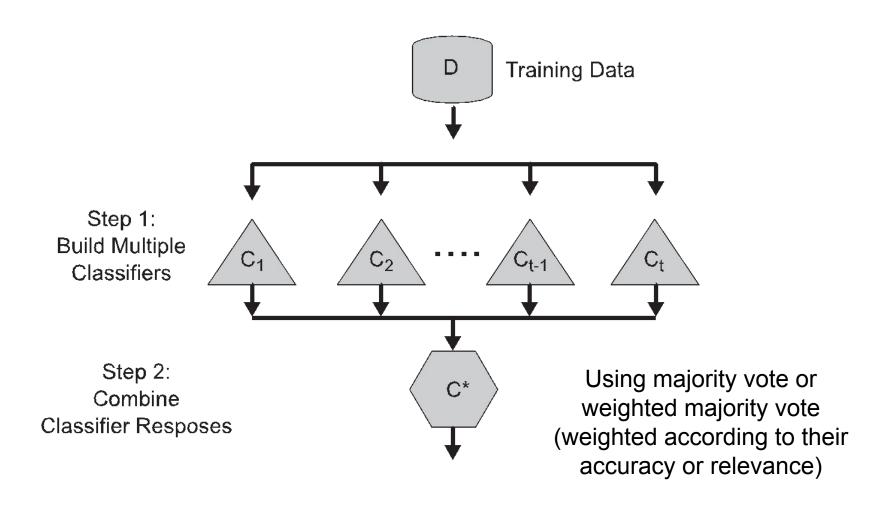

$$gen.error(m) = c_1 \times noise + bias(m) + c_2 \times variance(m)$$

Bias-Variance Trade-off and Overfitting

 Ensemble methods try to reduce the variance of complex models (with low bias) by aggregating responses of multiple base classifiers

General Approach of Ensemble Learning

Constructing Ensemble Classifiers

- By manipulating training set
 - Example: bagging, boosting
- By manipulating input features
 - Example: random forests
- By manipulating class labels
 - Example: error-correcting output coding
- By manipulating learning algorithm
 - Example: injecting randomness in ANN or decision tree

Bagging (Bootstrap AGGregatING)

Bootstrap sampling: sampling with replacement

| Original Data | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-------------------|---|---|----|----|---|---|----|----|---|----|
| Bagging (Round 1) | 7 | 8 | 10 | 8 | 2 | 5 | 10 | 10 | 5 | 9 |
| Bagging (Round 2) | 1 | 4 | 9 | 1 | 2 | 3 | 2 | 7 | 3 | 2 |
| Bagging (Round 3) | 1 | 8 | 5 | 10 | 5 | 5 | 9 | 6 | 3 | 7 |

- Build classifier on each bootstrap sample
- Probability of a training instance being selected in a bootstrap sample is:
 - \Box 1 (1 1/n)ⁿ (n: number of training instances)
 - □ ~0.632 when n is large

Bagging Algorithm

Algorithm 4.5 Bagging algorithm.

- 1: Let k be the number of bootstrap samples.
- 2: **for** i = 1 to k **do**
- 3: Create a bootstrap sample of size N, D_i .
- 4: Train a base classifier C_i on the bootstrap sample D_i .
- 5: end for
- 6: $C^*(x) = \underset{y}{\operatorname{argmax}} \sum_i \delta(C_i(x) = y).$

 $\{\delta(\cdot) = 1 \text{ if its argument is true and } 0 \text{ otherwise.}\}$

Consider 1-dimensional data set:

Original Data:

| X | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 | 1 |
|---|-----|-----|-----|-----|-----|-----|-----|-----|-----|---|
| у | 1 | 1 | 1 | -1 | -1 | -1 | -1 | 1 | 1 | 1 |

- Classifier is a decision stump (decision tree of size 1)
 - Decision rule: $x \le k$ versus x > k
 - Split point k is chosen based on entropy

| Baggir | ng Rour | nd 1: | | | | | | | | |

| Sign | 1 | 1 | 1 | -1 | -1 | -1 | -1 | 1 | 1 | 1 |

Predicted Class

 Bagging can also increase the complexity (representation capacity) of simple classifiers such as decision stumps

Boosting

- An iterative procedure to adaptively change distribution of training data by focusing more on previously misclassified records
 - Initially, all N records are assigned equal weights (for being selected for training)
 - Unlike bagging, weights may change at the end of each boosting round

Boosting

- Records that are wrongly classified will have their weights increased in the next round
- Records that are classified correctly will have their weights decreased in the next round

| Original Data | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|---------------------------|---|---|---|----|---|---|---|----|---|----|
| Boosting (Round 1) | 7 | 3 | 2 | 8 | 7 | 9 | 4 | 10 | 6 | 3 |
| Boosting (Round 2) | 5 | 4 | 9 | 4 | 2 | 5 | 1 | 7 | 4 | 2 |
| Boosting (Round 3) | 4 | 4 | 8 | 10 | 4 | 5 | 4 | 6 | 3 | 4 |

- Example 4 is hard to classify
- Its weight is increased, therefore it is more likely to be chosen again in subsequent rounds

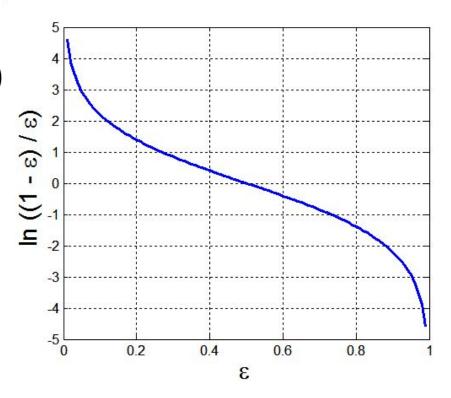

AdaBoost

- Base classifiers: C₁, C₂, ..., C_T
- Error rate of a base classifier:

$$\epsilon_i = \frac{1}{N} \sum_{j=1}^{N} w_j^{(i)} \, \delta(C_i(x_j) \neq y_j)$$

Importance of a classifier:

$$\alpha_i = \frac{1}{2} \ln \left(\frac{1 - \varepsilon_i}{\varepsilon_i} \right)$$

AdaBoost Algorithm

Weight update:

$$w_j^{(i+1)} = \frac{w_j^{(i)}}{Z_i} \times \begin{cases} e^{-\alpha_i} & \text{if } C_i(x_j) = y_j \\ e^{\alpha_i} & \text{if } C_i(x_j) \neq y_j \end{cases}$$

Where Z_i is the normalization factor

- If any intermediate rounds produce error rate higher than 50%, the weights are reverted back to 1/n and the resampling procedure is repeated
- Classification:

$$C^*(x) = \underset{y}{\operatorname{arg\,max}} \sum_{i=1}^{T} \alpha_i \delta(C_i(x) = y)$$

AdaBoost Algorithm

Algorithm 4.6 AdaBoost algorithm.

```
1: \mathbf{w} = \{w_j = 1/N \mid j = 1, 2, \dots, N\}. {Initialize the weights for all N examples.}
 2: Let k be the number of boosting rounds.
 3: for i = 1 to k do
 4:
       Create training set D_i by sampling (with replacement) from D according to w.
      Train a base classifier C_i on D_i.
 5:
       Apply C_i to all examples in the original training set, D.
 6:
      \epsilon_i = \frac{1}{N} \left[ \sum_j w_j \ \delta \left( C_i(x_j) \neq y_j \right) \right] {Calculate the weighted error.}
      if \epsilon_i > 0.5 then
 8:
          \mathbf{w} = \{w_i = 1/N \mid j = 1, 2, \dots, N\}. {Reset the weights for all N examples.}
     Go back to Step 4.
10:
       end if
11:
       \alpha_i = \frac{1}{2} \ln \frac{1 - \epsilon_i}{\epsilon_i}.
12:
       Update the weight of each example according to Equation 4.103.
13:
14: end for
15: C^*(\mathbf{x}) = \operatorname{argmax} \sum_{j=1}^T \alpha_j \delta(C_j(\mathbf{x}) = y).
```

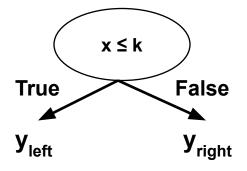

AdaBoost Example

Consider 1-dimensional data set:

Original Data:

| X | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 | 1 |
|---|-----|-----|-----|-----|-----|-----|-----|-----|-----|---|
| у | 1 | 1 | 1 | -1 | -1 | -1 | -1 | 1 | 1 | 1 |

- Classifier is a decision stump
 - Decision rule: x ≤ k versus x > k
 - Split point k is chosen based on entropy

AdaBoost Example

Training sets for the first 3 boosting rounds:

| Boostir | ng Roui | าd 1: | | | | | | | | |
|---------|---------|-------|-----|-----|-----|-----|-----|-----|-----|-----|
| Х | 0.1 | 0.4 | 0.5 | 0.6 | 0.6 | 0.7 | 0.7 | 0.7 | 8.0 | 1 |
| У | 1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | 1 | 1 |
| | | | | | | | | | | |
| Boostir | ng Roui | าd 2: | | | | | | | | |
| Х | 0.1 | 0.1 | 0.2 | 0.2 | 0.2 | 0.2 | 0.3 | 0.3 | 0.3 | 0.3 |
| У | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| | | | | | | | | | | |
| Boostir | ng Roui | าd 3: | | | | | | | | |
| Х | 0.2 | 0.2 | 0.4 | 0.4 | 0.4 | 0.4 | 0.5 | 0.6 | 0.6 | 0.7 |
| У | 1 | 1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 |
| | | | | | | | | | | |

Summary:

| Round | Split Point | Left Class | Right Class | alpha |
|-------|--------------------|------------|--------------------|--------|
| 1 | 0.75 | -1 | 1 | 1.738 |
| 2 | 0.05 | 1 | 1 | 2.7784 |
| 3 | 0.3 | 1 | -1 | 4.1195 |

Predicted Class

Random Forest Algorithm

- Construct an ensemble of decision trees by manipulating training set as well as features
 - Use bootstrap sample to train every decision tree (similar to Bagging)
 - Use the following tree induction algorithm:
 - At every internal node of decision tree, randomly sample p attributes for selecting split criterion
 - Repeat this procedure until all leaves are pure (unpruned tree)

Characteristics of Random Forest

- Base classifiers are unpruned trees and hence are unstable classifiers
- Base classifiers are decorrelated (due to randomization in training set as well as features)
- Random forests reduce variance of unstable classifiers without negatively impacting the bias
- Selection of hyper-parameter p
 - Small value ensures lack of correlation
 - High value promotes strong base classifiers
 - Common default choices: \sqrt{d} , $\log_2(d+1)$
